The if Statement

- **Control structure:** logical design that controls order in which set of statements execute
- **Sequence structure:** set of statements that execute in the order they appear
- **Decision structure:** specific action(s) performed only if a condition exists
 - Also known as selection structure

Addison-Wesley

PEARSON Copyright © 2015 Pearson Education, Inc. Publishing as Pearson Addison-Wesley

The if Statement (cont'd.)

- In flowchart, diamond represents true/false condition that must be tested
- Actions can be **conditionally executed**
 - Performed only when a condition is true
- **Single alternative decision structure:** provides only one alternative path of execution
 - If condition is not true, exit the structure

The if Statement (cont'd.)

Figure 3-1 A simple decision structure.

```

graph TD
    Start(( )) --> Cond{Cold outside}
    Cond -- True --> Action[Wear a coat.]
    Cond -- False --> Start
  
```

The if Statement (cont'd.)

- **Python syntax:**

```
if condition:
    Statement
    Statement
```
- **First line known as the if clause**
 - Includes the keyword `if` followed by condition
 - The condition can be true or false
 - When the `if` statement executes, the condition is tested, and if it is true the block statements are executed. otherwise, block statements are skipped

Boolean Expressions and Relational Operators

- **Boolean expression:** expression tested by if statement to determine if it is true or false

● Example: $a > b$
 ○ true if a is greater than b ; false otherwise

- **Relational operator:** determines whether a specific relationship exists between two values

● Example: greater than ($>$)

Boolean Expressions and Relational Operators (cont'd.)

- \geq and \leq operators test more than one relationship

○ It is enough for one of the relationships to exist for the expression to be true

- $=$ operator determines whether the two operands are equal to one another

○ Do not confuse with assignment operator ($=$)

- \neq operator determines whether the two operands are not equal

Boolean Expressions and Relational Operators (cont'd.)

Table 3-2 Boolean expressions using relational operators

| Expression | Meaning |
|------------|---------------------------------------|
| $x > y$ | Is x greater than y ? |
| $x < y$ | Is x less than y ? |
| $x \geq y$ | Is x greater than or equal to y ? |
| $x \leq y$ | Is x less than or equal to y ? |
| $x == y$ | Is x equal to y ? |
| $x != y$ | Is x not equal to y ? |

Boolean Expressions and Relational Operators (cont'd.)

- Using a Boolean expression with the $>$ relational operator

Figure 3-3 Example decision structure

Boolean Expressions and Relational Operators (cont'd.)

- Any relational operator can be used in a decision block

● Example: `if balance == 0`
 ● Example: `if payment != balance`

- It is possible to have a block inside another block

● Example: `if` statement inside a function
 ● Statements in inner block must be indented with respect to the outer block

The if-else Statement

- **Dual alternative decision structure: two possible paths of execution**

– One is taken if the condition is true, and the other if the condition is false

● Syntax:
`if condition:
 statements
else:
 other statements`

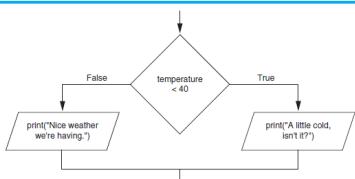

● `if` clause and `else` clause must be aligned
 ● Statements must be consistently indented

Comparing Strings

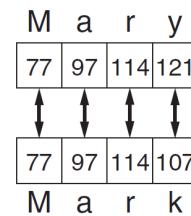

- Strings can be compared using the == and != operators
- String comparisons are case sensitive
- Strings can be compared using >, <, >=, and <=
 - Compared character by character based on the ASCII values for each character
 - If shorter word is substring of longer word, longer word is greater than shorter word

Nested Decision Structures and the if-elif-else Statement

- A decision structure can be nested inside another decision structure
 - Commonly needed in programs
 - Example:
 - Determine if someone qualifies for a loan, they must meet two conditions:
 - Must earn at least \$30,000/year
 - Must have been employed for at least two years
 - Check first condition, and if it is true, check second condition

Nested Decision Structures and the if-elif-else Statement (cont'd.)

- Important to use proper indentation in a nested decision structure
 - Important for Python interpreter
 - Makes code more readable for programmer
 - Rules for writing nested if statements:
 - else clause should align with matching if clause
 - Statements in each block must be consistently indented

Addison-Wesley

The if-elif-else Statement

- if-elif-else statement: special version of a decision structure

– Makes logic of nested decision structures simpler to write

– Can include multiple elif statements

– Syntax:

```
if condition1
    statements
elif condition2
    statements
else
    statements
```

Addison-Wesley

PEARSON

Copyright © 2015 Pearson Education, Inc. Publishing as Pearson Addison-Wesley

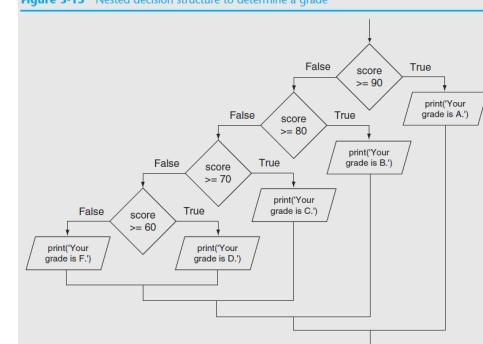

The if-elif-else Statement (cont'd.)

- Alignment used with if-elif-else statement:
 - if, elif, and else clauses are all aligned
 - Conditionally executed blocks are consistently indented
- if-elif-else statement is never required, but logic easier to follow
 - Can be accomplished by nested if-else
 - Code can become complex, and indentation can cause problematic long lines

Logical Operators

- Logical operators: operators that can be used to create complex Boolean expressions
 - and operator and or operator: binary operators, connect two Boolean expressions into a compound Boolean expression
 - not operator: unary operator, reverses the truth of its Boolean operand

Addison-Wesley
Is an imprint of
PEARSON

Copyright © 2015 Pearson Education, Inc. Publishing as Pearson Addison-Wesley

The and Operator

- Takes two Boolean expressions as operands

– Creates compound Boolean expression that is true only when both sub expressions are true

– Can be used to simplify nested decision structures

- Truth table for the and operator

| Expression | Value of the Expression |
|-----------------|-------------------------|
| false and false | false |
| false and true | false |
| true and false | false |
| true and true | true |

Addison-Wesley
Is an imprint of
PEARSON

Copyright © 2015 Pearson Education, Inc. Publishing as Pearson Addison-Wesley

The or Operator

- Creates compound Boolean expression that is true when either of the sub expressions is true
- Can be used to simplify nested decision structures

Truth table for the or operator

| Expression | Value of the Expression |
|-----------------|-------------------------|
| false and false | false |
| false and true | true |
| true and false | true |
| true and true | true |

Short-Circuit Evaluation

- Short circuit evaluation:** deciding the value of a compound Boolean expression after evaluating only one sub expression

- Performed by the or and and operators
 - For or operator: If left operand is true, compound expression is true. Otherwise, evaluate right operand
 - For and operator: If left operand is false, compound expression is false. Otherwise, evaluate right operand

Addison-Wesley
Is an imprint of
PEARSON

Copyright © 2015 Pearson Education, Inc. Publishing as Pearson Addison-Wesley

The not Operator

- Takes one Boolean expression as operand and reverses its logical value
 - Sometimes it may be necessary to place parentheses around an expression to clarify to what you are applying the not operator

Truth table for the not operator

| Expression | Value of the Expression |
|------------|-------------------------|
| true | false |
| false | true |

Checking Numeric Ranges with Logical Operators

- To determine whether a numeric value is within a specific range of values, use and
 - Example: $x \geq 10$ and $x \leq 20$
- To determine whether a numeric value is outside of a specific range of values, use or
 - Example: $x < 10$ or $x > 20$

Boolean Variables

- Boolean variable:** references one of two values, True OR False
 - Represented by bool data type
- Commonly used as flags**
 - Flag: variable that signals when some condition exists in a program
 - Flag set to False → condition does not exist
 - Flag set to True → condition exists

Summary

- This chapter covered:**
 - Decision structures, including:
 - Single alternative decision structures
 - Dual alternative decision structures
 - Nested decision structures
 - Relational operators and logical operators as used in creating Boolean expressions
 - String comparison as used in creating Boolean expressions
 - Boolean variables
